#### Abstract

The object of this paper is to describe the development of ideas pertaining to sample size and maximum likelihood estimators of parameters associated with a probability function or density function. About forty years ago we considered a Taylor type series for a maximum likelihood estimator $\hat{\theta}_{a}$ for $\theta_{a}$, there being $s$ parameters $\theta_{1}, \theta_{2}, \ldots, \theta_{s}$. First order bias and first order variance were included. Because of limitations in computer facilities, the skewness and kurtosis were avoided, and also because of the complicated structures involved. But toward the end of the 20th century an expression for the $N^{-2}$ ( $N$ the

sample size) term in the third central moment of $\hat{\theta}_{a}$ was found, and a
year later a rather complicated expression for the $N^{-3}$ term in the fourth central moment was discovered. The skewness and kurtosis expressions involved much heavier work in deriving expectations of products of log-derivatives of the probability function or density, especially when 3 or more parameters were involved. At this stage we used the Maple symbolic language to cope with the $N^{-1}$ and $N^{-2}$ biases, the $N^{-1}$ and $N^{-2}$ variances, the $N^{-2}$ third central moment, and the $N^{-3}$ fourth central moment. We use the $\sqrt{\beta_{1}}=\mu_{3} / \sigma^{3}$ to measure skewness. This ratio is location and scale free, and it takes into account the shape of the distribution involved. Since under normality
$\sqrt{\beta_{1}}=0$, we can set the observed value $\sqrt{\beta_{1}\left(\hat{\theta}_{a}\right)}$ for a parameter $\theta_{a}$, to a small value $\varepsilon$ and deduce a safe-sample size to achieve pseudonormality. Programs are provided in detail for the low order moments of a maximum likelihood estimator, simultaneous estimation being involved.

## 1. Introduction

Our study of small sample properties of maximum likelihood (m.l.) estimators started some forty years ago. We set up a Taylor type expansion for $s$ parameters $\theta_{1}, \theta_{2}, \ldots, \theta_{s}$, and in particular $\hat{\theta}_{a}, a=1$, $2, \ldots, s$. Expectations of powers of the derivatives of the logarithm of the density were derived, up to and including the fourth power. In view of the extensive algebra involved our thoughts became directed to computer implementation, especially for the skewness and kurtosis of estimators.

The 'References' include not only subjects pertinent to the present study, but also peripheral topics such as moment methods and divergent series. In addition summaries of previous studies on estimation problems are given in Appendix B.

Since the basic structure is set out clearly in a paper we read at the Prague (1973) Symposium on Asymptotic Statistics (Shenton and Bowman [51]), we now include an abbreviated version.

## 2. Asymptotic Statistics (Prague Symposium)

### 2.1. Introduction

Suppose a population consists of categorized data, the probability of an occurrence in the $j$ th class being $p_{j}(\theta)$, with $n_{j}$ observations for a sample of size $N$. We have given expressions (Bowman and Shenton [8]) for the $N^{-1}, N^{-2}$ terms in the bias of $\hat{\theta}$ (the m.l. estimator), $N^{-1}, N^{-2}$, $N^{-3}$ terms in $\mu_{2}(\hat{\theta}), N^{-2}, N^{-3}$ terms in $\mu_{3}(\hat{\theta}), N^{-2}, N^{-3}, N^{-4}$ terms in $\mu_{4}(\hat{\theta}), \mu_{2}, \mu_{3}, \mu_{4}$ being central moments. In certain special cases higher order terms in the moments can be found by special techniques. Previously, Haldane [35] and Haldane and Smith [36] discussed properties of the moments of m.l. estimators in the case of one and two parameters. Actually, as has been pointed out by Cox and Snell [31], Bartlet [3] gave expressions for the $N^{-1}$ biases in his paper on largesample confidence intervals.

Here we give the first few terms in the asymptotic expansion (Lagrange) for a m.l. estimator (mentioned by name by Haldane and Smith [36, p. 99]) in the single parameter case. The $N^{-2}$ biases and covariances in the multi-parameter case are also given with a brief outline of the derivation; these expressions have only appeared in report form previously (Bowman and Shenton [7, 8]). A number of miscellaneous asymptotic moments for m.l. and for comparison moment estimators, are included.

### 2.2. Taylor series approach

### 2.2.1. Single parameter

We assume that a population consists of a denumerable set of classes, there being $n_{j}$ relative observations in the $j$ th class for a sample of $N$ with $E n_{j}=p_{j}(\theta)$, where $p_{j}$ depends on the single parameter $\theta$. The log likelihood is proportional to

$$
\begin{equation*}
L(n, \theta)=\sum n_{j} \log p_{j}(\theta) \tag{1}
\end{equation*}
$$

summed over the classes. If $\hat{\theta}$ is the m.l. estimator, then under certain regularity conditions (with $L(\theta)$ for $L(n, \theta)$ )

$$
\begin{equation*}
L^{(1)}(\theta)+x L^{(2)}(\theta)+\frac{x^{2}}{2!} L^{(3)}(\theta)+\cdots=0 \tag{2}
\end{equation*}
$$

where $x=\hat{\theta}-\theta$. Now define

$$
c_{s}=L^{(s)}(\theta) / L^{(2)}(\theta), \quad s=1,2, \ldots
$$

so that $c_{2}=1$. Note that in general $E L^{(2)}(\theta) \neq 0$. Equation (2) may be written

$$
c_{1}+x\left\{1+\frac{x}{2!} c_{3}+\frac{x^{2}}{3!} c_{4}+\cdots\right\}=0
$$

whence from Lagrange's expansion, formally, for a well-behaved function $f(\cdot)$,

$$
f(x)=f(0)+\left.\sum_{1}^{\infty} \frac{1}{s!} \frac{d^{s-1}}{d x^{s-1}}\left\{\frac{-c_{1}}{1+\frac{x}{2} c_{3}+\cdots}\right\}^{s} f^{(1)}(x)\right|_{x=0}
$$

In particular

$$
\begin{equation*}
\hat{\theta}=\theta+\sum_{s=1}^{\infty} c_{1}^{s} C_{s} \tag{3}
\end{equation*}
$$

where

$$
\begin{aligned}
& C_{1}=-1, \quad C_{2}=-c_{3} / 2 \\
& C_{3}=\left(c_{4}-3 c_{3}^{2}\right) / 6 \\
& C_{4}=-\left(c_{5}-10 c_{3} c_{4}+15 c_{3}^{3}\right) / 24 \\
& C_{5}=\left(c_{6}-10 c_{4}^{2}-15 c_{3} c_{5}+105 c_{3}^{2} c_{4}-105 c_{3}^{4}\right) / 120 \\
& C_{6}=-\left(c_{7}-21 c_{3} c_{6}-35 c_{4} c_{5}+210 c_{3}^{2} c_{5}+280 c_{3} c_{4}^{2}-1260 c_{5}^{3} c_{4}+945 c_{3}^{5}\right) / 720
\end{aligned}
$$

and so on. But $L^{(s)}(n, \theta)=\sum n_{j}\left(d^{s} / d \theta^{s}\right) \log p_{j}$, and defining the discrepancies $n_{j}-p_{j}=\varepsilon_{j}$, we have

$$
\begin{aligned}
L^{(s)}(n, \theta) & =L p_{j} \frac{d^{s}}{d \theta^{s}} \log p_{j}+\sum \varepsilon_{j} \frac{d^{s}}{d \theta^{s}} \log p_{j} \\
& =L_{s}+l_{s}(\varepsilon)
\end{aligned}
$$

where in particular $L^{(1)}=l_{1}(\varepsilon)$. Hence

$$
c_{s}=\frac{\left(L_{s}+l_{s}(\varepsilon)\right)}{L_{2}} \sum_{r=0}^{\infty}\left(-l_{2}(\varepsilon) / L_{2}\right)^{r}
$$

and substitution in (3) and similar equations for $(\hat{\theta}-\theta)^{s}, s=2,3, \ldots$, gives an expression which after taking expectations leads to the noncentral moments of $\hat{\theta}$. Equation (3) can be powered digitally, and then the only further requirement is a scheme to produce expectations of low order products such as

$$
\prod_{s=1}^{m} l_{s}^{r_{s}}(\varepsilon)
$$

One possible approach to this problem is given by Bowman [6].

### 2.2.2. Multiple parameter case

## (a) $N^{-2}$ biases and covariances

We now assume $\theta$ in (1) to be an $h$-component vector. The asymptotic multivariate moments in general now become very complicated in structure. In addition, it does not appear to be easy to set up an appropriate multivariate version of Lagrange which would be readily manipulatable in this case (to get some idea of the situation for multivariate Lagrange, see (i) Good [34, pp. 499-517]; (ii) Shenton and Consul [53]; (iii) Consul and Shenton [29, pp. 13-23]).

The stochastic Taylor expansion for $\hat{\theta}_{a},(a=1,2, \ldots, h)$ is now

$$
\hat{\theta}_{a}=\theta_{a}+\phi_{1}^{a}+\frac{1}{2!} \phi_{2}^{a}+\frac{1}{3!} \phi_{3}^{a}+\cdots,
$$

where
(i) $\phi_{1}^{a}=\varepsilon_{r} \frac{\bar{\partial} \theta_{a}}{\partial n_{r}}, \phi_{2}^{a}=\varepsilon_{r} \varepsilon_{s} \frac{\bar{\partial}^{2} \theta_{a}}{\partial n_{r} \partial n_{s}}$, etc.;
(ii) $\varepsilon_{r}=n_{r}-p_{r}, \quad E \varepsilon_{r}=0$;
(iii) $\frac{\bar{\partial} \theta_{a}}{\partial n_{r}}=\left.\frac{\partial \hat{\theta}_{a}}{\partial n_{r}}\right|_{n_{r}=p_{r}, \hat{\theta}_{a}=\theta_{a}}$
and so.

## (b) Notational

We define the multivariate derivative

$$
\Gamma_{\alpha_{1} \alpha_{2} \cdots \alpha_{m}}^{r}=\frac{\partial^{m}}{\partial \theta_{\alpha_{1}} \partial \theta_{\alpha_{2}} \cdots \partial \theta_{\alpha_{m}}} \log p_{r},
$$

and summation being over classes,

$$
\begin{aligned}
\left(p_{r} \Gamma_{\alpha_{1} \alpha_{2} \cdots \alpha_{l}}^{r} \Gamma_{\beta_{1} \beta_{2} \cdots \beta_{m}}^{r} \Gamma_{\gamma_{1} \gamma_{2} \cdots \gamma_{n}}^{r}\right) & =\left(p \Gamma_{\alpha_{1} \alpha_{2} \cdots \alpha_{l}} \Gamma_{\beta_{1} \beta_{2} \cdots \beta_{m}} \Gamma_{\gamma_{1} \gamma_{2} \cdots \gamma_{n}}\right) \\
& =\left[\alpha_{1} \alpha_{2} \cdots \alpha_{l}, \beta_{1} \beta_{2} \cdots \beta_{m}, \gamma_{1} \gamma_{2} \cdots \gamma_{n}\right] .
\end{aligned}
$$

For example

$$
\begin{aligned}
& {[\alpha, \beta, \gamma]=\left(p \Gamma_{\alpha} \Gamma_{\beta} \Gamma_{\gamma}\right)=\sum_{r} p_{r} \frac{\partial \log p_{r}}{\partial \theta_{\alpha}} \frac{\partial \log p_{r}}{\partial \theta_{\beta}} \frac{\partial \log p_{r}}{\partial \theta_{\gamma}},} \\
& {[\alpha \beta, \gamma]=\left(p \Gamma_{\alpha \beta} \Gamma_{\gamma}\right)=\sum_{r} p_{r} \frac{\partial^{2} \log p_{r}}{\partial \theta_{\alpha} \partial \theta_{\beta}} \frac{\partial \log p_{r}}{\partial \theta_{\gamma}},} \\
& {[\alpha \beta \gamma]=\left(p \Gamma_{\alpha \beta \gamma}\right)=\sum_{r} p_{r} \frac{\partial^{3} \log p_{r}}{\partial \theta_{\alpha} \partial \theta_{\beta} \partial \theta_{\gamma}} .}
\end{aligned}
$$

(c) The likelihood equations for the estimates $\hat{\theta}_{a}$ of $\theta_{a}$

We have

$$
\begin{equation*}
n_{r} \hat{\Gamma}_{\alpha}^{r}=0 \quad(\alpha=1,2, \ldots, h) \tag{4}
\end{equation*}
$$

where $\hat{\Gamma}_{\alpha}^{r}=\partial \log p_{r}(\hat{\theta}) / \partial \hat{\theta}_{\alpha}$. Differentiating (4) partially with respect to $n_{r}$ gives

$$
\begin{equation*}
\hat{\Gamma}_{\alpha}^{r}+\left(n_{r} \hat{\Gamma}_{\alpha \beta}^{r}\right) \frac{\partial \hat{\theta}_{\beta}}{\partial n_{r}}=0, \tag{5}
\end{equation*}
$$

from which

$$
\begin{equation*}
\frac{\bar{\partial} \theta_{\alpha}}{\partial n_{r}}=L^{\alpha \beta} \Gamma_{\beta}^{r}, \tag{6}
\end{equation*}
$$

where

$$
\begin{aligned}
& L_{\alpha \beta}=-\left(p \Gamma_{\alpha \beta}\right)=\left(p \Gamma_{\alpha} \Gamma_{\beta}\right) \\
& L_{\alpha \beta} L^{\beta \gamma}=\varepsilon_{\alpha \gamma}(\text { Kronecker delta })
\end{aligned}
$$

so that $L^{\beta \alpha}$ refers to an element in the inverse matrix $\left[L_{\alpha \beta}\right]^{-1}$, where [ $L_{\alpha \beta}$ ] has $h$ rows and columns and is assumed nonsingular.

Returning to (5) and differentiating with respect to $n_{s}$, we have

$$
\hat{\Gamma}_{\alpha \beta}^{r} \frac{\partial \hat{\theta}_{\beta}}{\partial n_{s}}+\hat{\Gamma}_{\alpha \beta}^{s} \frac{\partial \hat{\theta}_{\beta}}{\partial n_{r}}+\left(n_{r} \hat{\Gamma}_{\alpha \beta \gamma}^{r}\right) \frac{\partial \hat{\theta}_{\beta} \partial \hat{\theta}_{\gamma}}{\partial n_{r} \partial n_{s}}+\left(n_{r} \hat{\Gamma}_{\alpha \beta}^{r}\right) \frac{\partial^{2} \hat{\theta}_{\beta}}{\partial n_{r} \partial n_{s}}=0,
$$

from which

$$
\begin{equation*}
L_{\alpha \beta} \frac{\bar{\partial}^{2} \theta_{\beta}}{\partial n_{r} \partial n_{s}}=L^{\beta \gamma} \Gamma_{\alpha \beta}^{r} \Gamma_{\gamma}^{s}+L^{\beta \gamma} \Gamma_{\alpha \beta}^{s} \Gamma_{\gamma}^{r}+[\alpha \beta \gamma] L^{\beta \delta} L^{\gamma \varepsilon} \Gamma_{\delta}^{r} \Gamma_{\varepsilon}^{s} . \tag{7}
\end{equation*}
$$

It will be seen since that partial differentiation is usually commutative, the right hand member of (7) should also have this property with respect to $r, s$. This is readily verified; in fact the last member of (7) under $r \leftrightarrow s$ is invariant, using $\delta \leftrightarrow \varepsilon, \gamma \leftrightarrow \beta$.

Similarly, expressions may be derived for the third and fourth multivariate derivatives and the associated values at $\hat{\theta}=\theta, \quad n_{r}=p_{r}$ (Bowman and Shenton [7, 8]).

## (d) Variances

For the covariances, writing $E_{2} \phi(\varepsilon)$ for the coefficient of $N^{-2}$ in $E \phi(\varepsilon)$, we have

$$
\begin{equation*}
E_{2}\left(\hat{\theta}_{a}-\theta_{a}\right)\left(\hat{\theta}_{b}-\theta_{b}\right)=\left(6 A_{12}+2 A_{13}+3 A_{22}\right) / 12 \tag{8}
\end{equation*}
$$

where

$$
\begin{aligned}
& A_{12}=E_{2}\left(\phi_{1}^{a} \phi_{2}^{b}+\phi_{2}^{a} \phi_{1}^{b}\right), \\
& A_{13}=E_{2}\left(\phi_{1}^{a} \phi_{3}^{b}+\phi_{3}^{a} \phi_{1}^{b}\right), \\
& A_{22}=E_{2} \phi_{2}^{a} \phi_{2}^{b} .
\end{aligned}
$$

From (6) and (7)

$$
\begin{align*}
E_{2} \phi_{1}^{a} \phi_{2}^{b} & =E_{2} \varepsilon_{r} \varepsilon_{s} \varepsilon_{t} L^{\alpha \beta} L^{\alpha b}\left\{L^{\gamma \zeta} \Gamma_{\beta}^{r} \Gamma_{\gamma}^{s} \Gamma_{\zeta}^{t}+L^{\gamma \zeta} \Gamma_{\beta}^{r} \Gamma_{\alpha \zeta}^{s} \Gamma_{\gamma}^{t}+[\alpha \gamma \zeta] L^{\delta \zeta} L^{\gamma \varepsilon} \Gamma_{\beta}^{r} \Gamma_{\varepsilon}^{s} \Gamma_{\delta}^{t}\right\} \\
& =2 L^{\alpha \beta} L^{\alpha b} L^{\gamma \varepsilon}[\alpha \varepsilon, \beta, \gamma]+2 L^{\alpha b}+L^{\alpha \beta} L^{b \alpha} L^{\delta \zeta} L^{\gamma \varepsilon}[\alpha \gamma \zeta][\beta, \delta, \varepsilon] . \tag{9}
\end{align*}
$$

Expectations of products of linear forms such as $\varepsilon_{1}^{r_{1}} \varepsilon_{2}^{r_{2}} \cdots \varepsilon_{k}^{r_{k}}$ present no particular problem, especially for low orders (see for example, Shenton [44] and Bowman [6]).

Expressions similar to (9) for $A_{13}, A_{22}$ may be set up, and substituting in (8) and simplifying finally leads to

$$
\operatorname{cov}_{2}\left(\hat{\theta}_{a}, \hat{\theta}_{b}\right)=\Theta_{1}+\Theta_{3}+\Theta_{4}
$$

where

$$
\begin{aligned}
\Theta_{1}= & -L^{a b} \\
\Theta_{3}= & l^{\alpha \beta} L^{b \alpha} L^{\gamma \delta}\{[\alpha \delta, \beta, \gamma]+[\beta \delta, \alpha, \gamma]+[\alpha \beta \gamma \delta]+3[\alpha \delta, \beta \gamma]+2[\alpha \beta \gamma, \delta] \\
& +[\beta \gamma \delta, \alpha] / 2+[\alpha \gamma \delta, \beta] / 2\},
\end{aligned}
$$

$$
\begin{aligned}
\Theta_{4}= & L^{a \alpha} L^{b \beta} L^{\gamma \delta} L^{\varepsilon \zeta}\{[\alpha \gamma \zeta][\beta, \delta, \varepsilon] / 2+[\beta \gamma \zeta][\alpha, \delta, \varepsilon] / 2 \\
& +[\alpha \beta \gamma][\delta \varepsilon \zeta]+5[\alpha \gamma \varepsilon][\beta \delta \zeta] / 2 \\
& +[\beta \gamma \zeta][\delta \varepsilon, \alpha]+[\alpha \gamma \zeta][\delta \varepsilon, \beta]+2[\alpha \beta \zeta][\gamma \varepsilon, \delta]+3[\beta \gamma \varepsilon][\alpha \zeta, \delta]+3[\alpha \gamma \varepsilon][\beta \zeta, \delta] \\
& +[\gamma \delta \varepsilon][\beta \zeta, \alpha] / 2+[\gamma \delta \varepsilon][\alpha \zeta, \beta] / 2+[\alpha \varepsilon, \delta][\gamma \zeta, \beta] \\
& +[\beta \varepsilon, \delta][\gamma \zeta, \alpha]+[\alpha \varepsilon, \beta][\gamma \zeta, \delta]+[\beta \varepsilon, \alpha][\gamma \zeta, \delta]+[\alpha \varepsilon, \gamma][\beta \delta \zeta]\} .
\end{aligned}
$$

In this expression the summation is over the Greek symbols, each of which takes all values from 1 to $h$, the number of parameters.

## (e) Biases

The $N^{-2}$ terms here are complicated, and after extensive algebra and simplification, we find

$$
\begin{align*}
E_{2} \hat{\theta}_{a}= & L^{\alpha \alpha} L^{\beta \gamma} B_{2}+L^{\alpha \alpha} L^{\beta \delta} L^{\gamma \varepsilon} B_{3}+L^{\alpha \alpha} L^{\beta \gamma} L^{\delta \zeta} L^{\varepsilon \eta} B_{4} \\
& +L^{a \alpha} L^{\beta \gamma} L^{\delta \varepsilon} L^{\zeta \eta} L^{\theta i} B_{5}, \tag{10}
\end{align*}
$$

where

$$
\begin{aligned}
2 B_{2}= & -[\alpha \beta \gamma]-2[\alpha \beta, \gamma], \\
8 B_{3}= & {[\alpha \beta \gamma \delta \varepsilon]+4[\beta \delta \varepsilon, \alpha \gamma]+8[\alpha \beta \gamma, \delta \varepsilon]+4[\alpha \beta \gamma \varepsilon, \delta]+4[\alpha \beta \gamma, \delta, \varepsilon]+8[\alpha \beta, \gamma \delta, \varepsilon], } \\
4 B_{4}= & (2[\alpha \delta \varepsilon \zeta][\beta \eta, \gamma]+2[\beta \delta \varepsilon \zeta][\alpha \gamma, \eta]+4[\alpha \beta \delta \varepsilon][\zeta \eta, \gamma]) \\
& +([\alpha \delta \varepsilon \zeta][\beta \gamma \eta]+[\alpha \beta \delta \varepsilon][\gamma \zeta \eta]+2[\beta \delta \varepsilon \eta][\alpha \gamma \zeta]) \\
& +(2[\beta \eta, \gamma \zeta][\alpha \delta \varepsilon]+4[\beta \varepsilon, \delta \eta][\alpha \gamma \zeta]+4[\alpha \gamma, \zeta \eta][\beta \delta \varepsilon]+2[\alpha \eta, \delta \varepsilon][\beta \gamma \zeta]) \\
& +(4[\alpha \varepsilon \zeta, \eta][\beta \delta, \gamma]+4[\alpha \varepsilon \zeta, \gamma][\beta \delta, \eta]+4[\beta \delta \varepsilon, \eta][\alpha \zeta, \gamma]) \\
& +(2[\alpha \beta \varepsilon, \eta][\gamma \delta, \zeta]+4[\beta \delta \varepsilon, \eta][\alpha \gamma, \zeta]+4[\alpha \beta \varepsilon, \zeta][\gamma \delta, \eta]+2[\delta \varepsilon \eta, \beta][\alpha \gamma, \eta]) \\
& +(4[\alpha \eta, \gamma \zeta][\delta \varepsilon, \beta]+4[\delta \varepsilon, \zeta][\alpha \eta, \beta]+4[\alpha \eta, \delta \varepsilon][\gamma \zeta, \beta]) \\
& +(4[\varepsilon \zeta, \beta \delta][\alpha \gamma, \eta]+2[\alpha \beta, \zeta \eta][\gamma \delta \varepsilon])+2[\alpha \beta \delta \varepsilon][\gamma, \zeta, \eta] / 3, \\
8 B_{5}= & {[\alpha \delta \zeta]\{[\beta \gamma \varepsilon][\eta \theta i]+2[\gamma \varepsilon \theta][\beta \eta i]+4[\beta \varepsilon \eta][\gamma \theta i]+8[\beta \eta \theta][\gamma \varepsilon i]} \\
& +2[\beta \gamma \varepsilon][\eta \theta, i]+4[\gamma \varepsilon \theta][\beta \eta, i]+2[\eta \theta i][\beta \varepsilon, \gamma]+4[\gamma \eta \theta][\beta \varepsilon, i]
\end{aligned}
$$

$$
\begin{aligned}
& +8[\beta \eta \theta][\gamma \varepsilon, i]+8[\beta \eta \theta][\gamma i, \varepsilon]+8[\beta \varepsilon \eta][\gamma \theta, i]+8[\gamma \varepsilon \theta][\beta \eta, i] \\
& +4[\gamma \theta i][\beta \eta, \varepsilon]+4[\eta \theta, i][\beta \varepsilon, \gamma]+4[\beta \varepsilon, i][\eta \theta, \gamma]+8[\eta \theta, \beta][\gamma i, \varepsilon] \\
& +8[\eta \theta, \varepsilon][\gamma i, \beta]+4[\beta \varepsilon \theta][\gamma, \eta, i]\}+[\gamma \delta i]\{8[\beta \eta \theta][\alpha \varepsilon, \zeta] \\
& +4[\beta \zeta \theta][\alpha \varepsilon, \theta]+8[\alpha \varepsilon, \theta][\beta \eta, \zeta]+8[\alpha \varepsilon, \zeta][\beta \eta, \theta]+8[\alpha \zeta, \beta][\varepsilon \eta, \theta]\} .
\end{aligned}
$$

It should be remarked that (10) is an expression involving four summatory terms and these are written as "products" merely to abbreviate.

## 3. Extension to the Skewness and Kurtosis

### 3.1. New formula for skewness

We see that (Bowman and Shenton [7, 8]) $N^{-2}$ terms are given for bias and covariance of m.l. estimators; another account of these is given in Shenton and Bowman [52]. At that time (1960-1988) we found the problem of skewness of m.l. estimators, in the simultaneous case too complicated to consider. But after some time a formula for $\mu_{32}\left(\hat{\theta}_{a}\right)$ was set up; here the estimator in question is $\theta_{a}, \hat{\theta}_{a}$ being the m.l. estimator, $\mu_{32}$ being the coefficient of $N^{-2}$ in the third central moment of $\hat{\theta}_{a}, a$ taking the values 1 to $s, s$ being the number of parameters. For some time, the form lay in limbo. But a little later we took a second look at the correction term involved and discovered the new formula

$$
\mu_{32}\left(\hat{\theta}_{a}\right)=L^{a 1} L^{a 2} L^{a 3}\{[1,2,3]+3[123]+6[12,3]\}
$$

given in Bowman and Shenton [19, p. 2751]. Here, 1, 2,3 run through the values 1 to $s$. A year later we defined in Bowman and Shenton [21], the formula for the kurtosis (both skewness and kurtosis being measured by sample moment ratios), a rather complicated formula to say the least.

### 3.2. Formula for kurtosis

The formula for $\mu_{43}\left(\hat{\theta}_{a}\right)$ was introduced by Bowman and Shenton [21], namely

$$
\begin{equation*}
\mu_{43}\left(\hat{\theta}_{a}\right)=A_{40}+2 A_{32}+\frac{2}{3} A_{33}+\frac{6}{4} A_{22} \tag{11}
\end{equation*}
$$

For $A_{40}, A_{32}, A_{33}$, and $A_{22}$, we have

$$
\begin{aligned}
A_{40}= & L^{a 1} L^{a 2} L^{a 3} L^{a 4}[1,2,3,4]-3\left(L^{a a}\right)^{2} \\
A_{32}= & 2 L^{a 1} L^{23} L^{a 4} L^{a 5} L^{a 6}\{[12,3][4,5,6]+[12,4][3,5,6] \\
& +[12,5][3,4,6]+[12,6][3,4,5]\} \\
& +12\left(L^{a \alpha}\right)^{2}+6 L^{a 1} L^{a 2} L^{a 3} L^{a 4}[12,3,4]+6 L^{a a} L^{a 1} L^{23} L^{a 4}[12,3,4] \\
& +[123][4,5,6]\left\{L^{a 1} L^{23} L^{a 4} L^{a 5} L^{a 6}+6 L^{a 1} L^{a 2} L^{34} L^{a 5} L^{a 6}\right. \\
& \left.+3 L^{a a} L^{a 1} L^{24} L^{35} L^{a 6}\right\} \\
& -\left\{L^{a 1} L^{23}(2[12,3]+[123])\right\}\left\{L^{a 4} L^{a 5} L^{a 6}[4,5,6]\right\}, \\
A_{33}= & E_{3}\left(\phi_{1}^{a}\right)^{3} \phi_{3}^{a}=\mathcal{A}_{1}+\mathcal{A}_{2}+\mathcal{A}_{3}+\mathcal{A}_{4},
\end{aligned}
$$

where

$$
\begin{aligned}
\mathcal{A}_{1}= & 18 L^{a a} L^{a 1} L^{24} L^{a 3}[123,4]+9 L^{a a} L^{a 1} L^{23} L^{a 4}[123,4] \\
& +18 L^{a 1} L^{a 2} L^{a 3} L^{a 4}[123,4] \\
\mathcal{A}_{2}= & -18\left(L^{a a}\right)^{2}+18 L^{a a} L^{a 1} L^{23} L^{a 4}[12,34] \\
& +36 L^{a a} L^{a 1} L^{23} L^{45} L^{a 6}[12,5][34,6]+36 L^{a 1} L^{23} L^{a 4} L^{a 5} L^{a 6}[12,5][34,6] \\
& +[345][12,6] L^{\alpha 1}\left\{18 L^{\alpha a} L^{23} L^{46} L^{a 5}+9 L^{a a} L^{23} L^{45} L^{a 6}\right. \\
& \left.+18 L^{23} L^{a 4} L^{a 5} L^{a 6}\right\}, \\

$$

## 4. Some Illustrative Examples

### 4.1. The two parameter gamma density, location known

Probability function is

$$
g(x, a, \rho)=\frac{e^{-x / a}(x / a)^{\rho-1}}{a \Gamma(\rho)} \quad(x>0, a>0, \rho>0)
$$

Bowman and Shenton [16] gave formulas and numerical examples for the m.l. moments $\left(\mu_{1}^{\prime}, \mu_{2}, \mu_{3}, \mu_{4}\right)$ of $\hat{a}$, the scale estimator, and $\hat{\rho}$, the shape estimator, each for up to the terms $N^{-6}$. We were very fortunate in finding those results with a completely independent approach, providing a check. The m.l. moments for $\hat{\alpha}$, and $\hat{\rho}$ are given in Table 1 and Table 2 (Bowman and Shenton [21]).
Table 1. Comparison of two methods of evaluating $\mu_{21}$ and $\mu_{22}(a=1)$

|  | $\hat{a}$ |  | $\hat{\rho}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\rho$ |  |  | $\mu_{21} / a^{2}$ | $\mu_{22} / a^{2}$ | $\mu_{21} / \rho^{2}$ |
| 5.0 | $m$ | 2.0759 | -1.9549 | 1.8759 | $\mu_{22} / \rho^{2}$ |
|  | $c m$ | 2.0759 | -1.9549 | 1.875912 | 20.472 |
|  |  |  |  |  |  |

Table 2. Comparison of two methods of evaluating $\mu_{32}$ and $\mu_{43}(a=1)$

|  |  | $\hat{a}$ |  | $\hat{\rho}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\rho$ |  | $\mu_{32} / a^{3}$ | $\mu_{43} / a^{4}$ | $\mu_{32} / \rho^{3}$ | $\mu_{43} / \rho^{4}$ |
| 0.1 | $m$ | 267.82 | 10259.00 | $4.9762 \times 10^{-3}$ | $90.535 \times 10^{-4}$ |
|  | $c m$ | 267.8224 | 10259.2093 | 0.0050 | $90.5352 \times 10^{-4}$ |

| 1.0 | $m$ | 15.2599 | 128.3511 | 10.4686 | 280.8125 |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $c m$ | 15.2599 | 128.3511 | 10.4685 | 280.8125 |
| 5.0 | $m$ | 8.1392 | 35.403 | 14.506 | 440.92 |
|  | $c m$ | 8.1392 | 35.4035 | 14.5062 | 440.9175 |
| 50.0 | $m$ | 8.0813 | 24.905 | 15.841 | 497.18 |
|  | $c m$ | 8.0813 | 24.9048 | 15.8410 | 497.1785 |

( $m$ refers to the Taylor series approach given in Bowman and Shenton [16, 18]; cm refers to the present approach using the covariance matrix).

The agreement is quite satisfactory. In passing note that moments $E(\hat{\rho}-\rho) / \rho, \operatorname{Var}(\hat{\rho} / \rho), \mu_{3}(\hat{\rho} / \rho), \mu_{4}(\hat{\rho} / \rho)$ to order $N^{-1}, N^{-2}, \ldots, N^{-6}$ are given in Bowman and Shenton [18, pp. 63-68].

### 4.2. The three parameter gamma density

Probability function is

$$
g(x ; s, a, \rho)=\frac{e^{-y}(y / a)^{\rho-1}}{a \Gamma(\rho)} \quad(y=x-s, x>s, a>0, \rho>0)
$$

In this case the additional parameter is $s$, referring to location. Details of problems relating to the m.l. estimators ( $\hat{s}, \hat{a}, \hat{\rho}$ ) are given in Bowman and Shenton [23]. At this time we were thinking that sample size could be related not only to the skewness (scale and location free), but also to the variances in the form $\mu_{22} / \mu_{21}$, second order term to first order term. In the paper on page 397 the ratio $R(\hat{t})=\mu_{22}(\hat{t}) / \mu_{21}(\hat{t}), t$ referring to $\hat{a} / a, \hat{\rho}$, and $\hat{s} / a$, is set at a half, in all cases for $\rho>4$ (moments of the m.l. estimators are unreliable unless $\rho>4$ ). For $\rho=6, s=0, a=1$, sample sizes are 429,462 , and 348 for $\hat{s} / a$, $\hat{\rho}$, and $\hat{a} / a$ respectively.

Table 3 is an extension of Table III in Bowman and Shenton [23]; the extension refers to $\rho=25,30$, and 35 . If the reader now considers the
moments of the estimators for $\rho=5(5)(35)$ it will be suggested that the skewness $\sqrt{\beta_{1}(\hat{\rho})}$ tends to a finite limit, so that for large $\rho$ there is not asymptotic normality.

Table 3. Asymptotic moment profile $(a=1, s=0)$, gamma density

|  | $\rho$ | $\mu_{11}^{\prime}$ | $\mu_{21}$ | $\mu_{22}$ | $\mu_{22} / \mu_{21}$ | $\sqrt{\beta_{11}}$ | K |

|  | 25.0 | -653.7693 | 19338.1066 | 5582919. | 288.70 | $-34.72$ | 1913.89 |
|  | 30.0 | -1010.2007 | 34532.1054 | 11984219. | 347.05 | -38.46 | 2336.54 |
|  | 35.0 | $-1441.5755$ | 56126.1046 | 22785548. | 405.97 | -41.85 | 2758.44 |

In a simulation study, not designed to fit in with the present study, (Bowman and Shenton [18, p. 136]) give the following moments of the m.l. estimators for a sample of $N=500$ (Table 4).

Table 4. Variability of moments over simulation runs

|  | $\hat{s}$ | $\hat{a}$ | $\hat{\rho}$ |
| :---: | :---: | :---: | :---: |
| Mean | 0.011 | 1.015 | 6.083 |
|  | $(0.044)$ | $(1.018)$ | $(5.996)$ |
| S.D. | 0.583 | 0.136 | 1.458 |
|  | $(0.516)$ | $(0.127)$ | $(1.226)$ |
| $\sqrt{\beta_{1}}$ | -0.853 | $(0.175)$ | 1.43 |
|  | $(0.441)$ | 3.15 | $(0.848)$ |
| $\beta_{2}$ | 4.80 | $(3.46)$ | $(4.468)$ |

(In this table, sampling is from a distribution with $s=0, a=1$, and $\rho=6$. Parenthetic entries refer to theoretical values, derived from Table III in Bowman and Shenton [23]. The simulation values are based on 5 cycles, each cycle consisting of 4,000 replications).

The agreement is fairly satisfactory. Discrepancies in the kurtosis may be expected since in practice $\beta_{2}$ may easily be in the range 1 to 20 .

### 4.3. The Weibull distribution, two parameter case

The density is

$$
f(x ; a, b, c)=\frac{c}{b} y^{c-1} e^{-y^{c}} \quad(x>a, y=(x-a) / b, b>0, c>0)
$$

We assume that $a$ is known and consider low order moments of the m.l. estimators $\hat{b}$ of $b, \hat{c}$ of $c$. As might be expected, polygamma functions such as the Psi function and its derivatives occur. We have (Bowman and Shenton [22]);

For $\hat{c}$

$$
\mu_{11}^{\prime}(\hat{c}, b)=c[-\zeta(3)+3 \zeta(2)]\lfloor\zeta(2)]^{2}=1.3795 c
$$

$$
\begin{aligned}
& \mu_{21}(\hat{c}, b)=6 c^{2} / \pi^{2}=0.6079 c^{2}, \quad \mu_{22}(\hat{c}, b)=\mu_{21} \times 6.3161=3.8398 c^{2} \\
& \mu_{32}(\hat{c}, b)=216 c^{3}\left(\pi^{2}-2 \zeta(3)\right) / \pi^{6}=1.6773 c^{3}, \quad \sqrt{\beta_{11}(\hat{c}, b)}=3.5386 \\
& \mu_{42}(\hat{c}, b)=3 \mu_{21}^{2}, \quad \mu_{43}(\hat{c}, b)=18.2992 c^{4}-c^{3}, \quad K(\hat{c}, b)=11.6174-2.7033 / c .
\end{aligned}
$$

For $\hat{b}$,

$$
\mu_{11}^{\prime}(\hat{b})=\frac{b}{c}\left\{\frac{-q \zeta(3)-D^{2}+A D-B q}{\zeta(2)^{2}}+\frac{D}{c 2 \zeta(2)}\right\}
$$

where

$$
\begin{aligned}
& D=\zeta(2)+[\psi(2)]^{2} \\
& q=1+p=1+\psi(1), \quad(\psi(1)=-\gamma) \\
& A=2 p^{2}+6 p+9 / 2 \\
& B=p^{3}+5 p^{2}+15 p / 2+7 / 2=q\left(p^{2}+4 p+7 / 2\right)
\end{aligned}
$$

An alternative formula to this is

$$
\begin{aligned}
& \mu_{11}^{\prime}(\hat{b})=\frac{b}{c}\left\{\frac{-\zeta(3)+\zeta(3) \gamma-\zeta(2)^{2}+\frac{5}{12} \pi^{2}-\frac{1}{3} \pi^{2} \gamma}{\zeta(2)^{2}}+\frac{\zeta(2)+\psi(2)^{2}}{c 2 \zeta(2)}\right\} \\
& \mu_{11}^{\prime}(\hat{b}, c)=\frac{b}{c}\left\{-0.3698+\frac{0.5543}{c}\right\} \\
& \mu_{21}(\hat{b}, c)=\left\{1+\frac{[\psi(2)]^{2}}{\psi_{1}(1)}\right\}\left(\frac{b}{c}\right)^{2}=1.1087\left(\frac{b}{c}\right)^{2} \\
& \mu_{22}(\hat{b}, c)=\frac{b^{2}}{c^{2}}\left[0.3624-\frac{1.9881}{c}+\frac{1.8429}{c^{2}}\right] \\
& \mu_{32}(\hat{b}, c)=\frac{b^{3}\left(c G_{1}+G_{2}\right)}{c^{4} \pi^{6}}=\frac{b^{3}}{c^{3}}\left[-1.1686+\frac{3.6873}{c}\right] \\
& \sqrt{\beta_{11}(\hat{b}, c)}=-1.0011+\frac{3.1587}{c}
\end{aligned}
$$

$$
\begin{aligned}
& \mu_{42}(\hat{b}, c)=3 \mu_{21}^{2}, \quad \mu_{43}(\hat{b}, c)=\frac{b^{4}}{c^{4}}\left[-24.3889-\frac{34.3604}{c}+\frac{34.0696}{c^{2}}\right] \\
& K(\hat{b}, c)=-21.8038-\frac{17.1924}{c}+\frac{17.7397}{c^{2}},
\end{aligned}
$$

where

$$
\begin{aligned}
G_{1}= & 108 \pi^{2}-1296 \gamma^{2} \zeta(3)+1296 \gamma \zeta(3)+432 \gamma^{3} \zeta(3)-216 \pi^{2} \gamma+108 \pi^{2} \gamma^{2} \\
& -18 \pi^{4} \gamma^{2}+36 \pi^{4} \gamma-\pi^{6}-432 \zeta(3)-18 \pi^{4}, \\
G_{2}= & 36 \pi^{4}+3 \pi^{6}-72 \pi^{4} \gamma+36 \pi^{4} \gamma^{2}-432 \pi^{2} \gamma^{3}+108 \pi^{2} \gamma^{4} \\
& +648 \pi^{2} \gamma^{2}-432 \pi^{2} \gamma+108 \pi^{2}
\end{aligned}
$$

( $\zeta$ is the zeta function, $\gamma$ is Euler's constant).
To check on these results, sample sizes of 50,100 , and 200 were considered using 50,000 cycles for $n=50,25,000$ cycles in the cases for $c=1,2,3,4,5$.

The comparisons with theory are given in Table 5, for $n=200, a=0, b=1$.

Table 5. Comparison of theoretical and simulation moments for $\hat{b}$ and $\hat{c}$

| $\hat{b}$ |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $c$ | $\mu_{1}$ | $\sigma$ | $\sqrt{\beta_{1}}$ | $\beta_{2}$ | $\mu_{1}$ | $\sigma$ | $\sqrt{\beta_{1}}$ | $\beta_{2}$ |
| 2 | T | 0.99977 | 0.0372 | 0.0409 | 2.8702 | 2.0138 | 0.1120 | 0.2502 |
| 3.0516 |  |  |  |  |  |  |  |  |
|  | S | 0.99990 | 0.0372 | 0.0591 | 2.9863 | 2.0156 | 0.1121 | 0.2582 |
| 5 | T | 0.99974 | 0.0149 | -0.0261 | 2.8773 | 5.0345 | 0.2800 | 0.2502 |
| 3.0554 |  |  |  |  |  |  |  |  |
| S | 0.99979 | 0.0149 | -0.0075 | 2.9886 | 5.0390 | 0.2802 | 0.2582 | 3.0836 |

( $\mathrm{T}=$ Theory, $\mathrm{S}=$ Simulation: For the theoretical entries parameters $\hat{b}$ and $\hat{c}, \mu_{1}^{\prime}(\hat{t})=t+\mu_{11}^{\prime}(\hat{t}) / N$, and similarly for $\sigma(\hat{t})=\sqrt{\mu_{21} / N+\mu_{22} / N^{2}}$.

Considering the skewness and kurtosis in both cases, the distributions are nearly normal in the sense that $\sqrt{\beta_{1}}$ is approximately zero and $\beta_{2}$ is approximately 3.

NAG library random number generator was used in the simulation study. Check on the basic random number generator gave about 3-4 digit accuracy for the first 4 moments of the Weibull distribution.

The agreement is good for $\hat{c}$ moments, satisfactory altogether.

### 4.4. The Weibull distribution and 3 parameters estimated by m.l.

In this case the asymptotic moments are complicated and involve considerable effort in algebraic manipulation. Here are examples:

$$
\begin{aligned}
& \operatorname{Var}_{1}(\hat{a})=b^{2} \psi_{1}(1) / \Delta(c) \\
& \operatorname{Var}_{1}(\hat{b})=b^{2}\left(C G-J^{2}\right) / \Delta(c) \\
& \operatorname{Var}_{1}(\hat{c})=c^{4}\left[C-\Gamma^{2}(2-1 / c)\right] / \Delta(c) \\
& \operatorname{Cov}_{1}(\hat{a}, \hat{b})=-b^{2}[G \Gamma(2-1 / c)+J \psi(2)] / \Delta(c) \\
& \operatorname{Cov}_{1}(\hat{a}, \hat{c})=-b c^{2}[\psi(2) \Gamma(2-1 / c)+J] / \Delta(c) \\
& \operatorname{Cov}_{1}(\hat{b}, \hat{c})=b c^{2}[\psi(2) C+\Gamma(2-1 / c) J] / \Delta(c)
\end{aligned}
$$

where

$$
\begin{aligned}
& \Delta(c)=c^{2}\left[\psi_{1}(1) C-\Gamma^{2}\left(2-\frac{1}{c}\right) G-J^{2}-2 \Gamma\left(2-\frac{1}{c}\right) \psi(2) J\right] \\
& C(c)=\Gamma\left(1-\frac{2}{c}\right) \frac{(c-1)^{2}}{c^{2}} \\
& J(c)=\Gamma\left(2-\frac{1}{c}\right)\left[\frac{1}{c-1}-\psi\left(2-\frac{1}{c}\right)\right] \\
& G=\psi_{1}(1)+[\psi(2)]^{2}
\end{aligned}
$$

To highlight the advantages of the Maple symbolic approach we give here further examples of the algebraic background.

$$
\Delta(c)=c^{2}\left\{\psi_{1}(1)\left[C(c)-\Gamma^{2}\left(2-\frac{1}{c}\right)\right]-H^{2}(c)\right\}
$$

where

$$
H(c)=\Gamma\left(2-\frac{t}{2}\right) \psi_{2}(2)+J(c), \quad J(c)=\Gamma\left(2-\frac{1}{c}\right)\left[\frac{1}{c-1}-\psi\left(2-\frac{1}{c}\right)\right](c>2)
$$

Defining $t=2 / c(0<t<1)$ we have

$$
H(c)=\Gamma\left(2-\frac{t}{2}\right)\left[\psi(1)-\psi\left(1-\frac{t}{2}\right)\right]=-\Gamma\left(2-\frac{t}{2}\right) \sum_{s=1}^{\infty}\left(-\frac{t}{2}\right)^{s} \frac{\psi_{s}(1)}{s!}
$$

After some simplification we find

$$
\operatorname{Var}_{1}(\hat{c}) \sim \frac{(c-1)^{2}\left(A_{0}+A_{1} t+A_{2} t^{2}+A_{3} t^{3}+\cdots\right)}{B_{0}+B_{1} t+B_{2} t^{2}+B_{3} t^{3}+\cdots}
$$

where

$$
\begin{aligned}
A_{0}= & A_{1}=0, \quad A_{2}=\pi^{2} / 24, \quad A_{3}=\pi^{2} \gamma / 24+\zeta(3) / 4 \\

\end{aligned}
$$

Numerically

$$
\frac{\operatorname{Var}_{1}(\hat{c})}{c^{4}} \sim 0.488214-\frac{0.929894}{c}+\frac{0.790780}{c^{2}}-\frac{0.566106}{c^{3}}
$$

These expressions were set up partly by using the Maple system. For large $c$

$$
\operatorname{Var}_{1}(\hat{c}) \sim \lambda(c-1)^{2} c^{2} \quad(c \rightarrow \infty)
$$

where $\lambda=4 \zeta(2) /\left[11 \zeta(4) \zeta(2)-4 \zeta^{2}(3)\right]=0.47665188$. Similarly

$$
\operatorname{Var}_{1}(\hat{a}) \sim \lambda b^{2} c^{2}, \quad \operatorname{Var}_{1}(\hat{b}) \sim \lambda b^{2}(c-1)^{2} \quad(c \rightarrow \infty)
$$

This excerpt is only a part of the computer input required for the implementation of the computer program (FORTRAN version program). Note that various aspects of the Weibull distribution have been considered by Dubay [33]. In the next section we describe the Maple factor.

## 5. The Advancement of Symbolic Computer Languages

These languages appeared on the scientific horizon about four decades ago. Formac was introduced by IBM but it had a short life in favor of main frame advances. A small group of researchers, sponsored by Dr. J. L. Carman (Head of the Computer Center, University of Georgia) and led by Dr. Juris Reinfelds, connected an electric typewriter to an IBM1620; difficulties arose because climate control was neglected. Reinfelds was mainly interested in algebraic processes, and Shenton and Hutcheson suggested a statistical problem, that of converting crude moments into cumulants. Examples are given below:

## Crude Moments into Cumulants

## Order one

$$
\mu_{1}^{\prime}=+\kappa_{1}
$$

## Order two

$$
\begin{aligned}
& \mu_{2}^{\prime}=+\kappa_{2}+\kappa_{1}^{2} \\
& \mu_{11}^{\prime}=+\kappa_{11}+\kappa_{10} \kappa_{01} .
\end{aligned}
$$

## Order three

$$
\begin{aligned}
& \mu_{3}^{\prime}=+\kappa_{3}+3 \kappa_{1}^{2} \kappa_{1}+\kappa_{1}^{3} \\
& \mu_{21}^{\prime}=+\kappa_{21}+2 \kappa_{11} \kappa_{10}+\kappa_{20} \kappa_{01}+\kappa_{10}^{2} \kappa_{01}, \\
& \mu_{111}^{\prime}=+\kappa_{111}+\kappa_{011} \kappa_{100}+\kappa_{110} \kappa_{001}+\kappa_{101} \kappa_{010}+\kappa_{100} \kappa_{001} \kappa_{010} .
\end{aligned}
$$

## Order four

$$
\begin{aligned}
\mu_{4}^{\prime}=+ & \kappa_{4}+4 \kappa_{3} \kappa_{1}+3 \kappa_{2}^{2}+6 \kappa_{2} \kappa_{1}^{2}+\kappa_{1}^{4}, \\
\mu_{31}^{\prime}= & +\kappa_{31}+3 \kappa_{21} \kappa_{10}+\kappa_{30} \kappa_{01}+3 \kappa_{20} \kappa_{11}+3 \kappa_{11} \kappa_{10}^{2} \\
& +3 \kappa_{20} \kappa_{10} \kappa_{01}+\kappa_{10}^{3} \kappa_{01}, \\
\mu_{22}^{\prime}=+ & \kappa_{22}+2 \kappa_{12} \kappa_{10}+2 \kappa_{21} \kappa_{01}+2 \kappa_{11}^{2}+\kappa_{20} \kappa_{02} \\
& +\kappa_{02} \kappa_{10}^{2}+4 \kappa_{11} \kappa_{10} \kappa_{01}+\kappa_{20} \kappa_{01}^{2}+\kappa_{10}^{2} \kappa_{01}^{2}, \\
\mu_{211}^{\prime}= & +\kappa_{211}+2 \kappa_{111} \kappa_{100}+\kappa_{201} \kappa_{010}+\kappa_{210} \kappa_{001}+2 \kappa_{110} \kappa_{101}+\kappa_{200} \kappa_{011} \\
& +\kappa_{011} \kappa_{100}^{2}+2 \kappa_{101} \kappa_{100} \kappa_{010}+2 \kappa_{110} \kappa_{100} \kappa_{001} \\
& +\kappa_{200} \kappa_{010} \kappa_{001}+\kappa_{100}^{2} \kappa_{010} \kappa_{001}, \\
\mu_{1111}^{\prime}= & +\kappa_{1111}+\kappa_{0111} \kappa_{1000}+\kappa_{1110} \kappa_{0001}+\kappa_{1011} \kappa_{0100} \\
& +\kappa_{1101} \kappa_{0010}+\kappa_{0101} \kappa_{1010}+\kappa_{1100} \kappa_{0011} \\
& +\kappa_{1001} \kappa_{0110}+\kappa_{0110} \kappa_{1000} \kappa_{0001}+\kappa_{0011} \kappa_{1000} \kappa_{0100} \\
& +\kappa_{1010} \kappa_{0001} \kappa_{0100}+\kappa_{0101} \kappa_{1000} \kappa_{0010} \\
& +\kappa_{1100} \kappa_{0001} \kappa_{0010}+\kappa_{1001} \kappa_{0100} \kappa_{0010}+\kappa_{1000} \kappa_{0001} \kappa_{0100} \kappa_{0010} .
\end{aligned}
$$

More details are given in the report "Tables of Crude Moments Expressed in terms of Cumulants" by Kratky, Reinfelds, Hutcheson, and Shenton, Computer Center, University of Georgia; Computer Center Report 1972(1). On the first page we find the quotation "The Marquis gazed a Moment, and nothing did he say", William Edmondstone Aytoun (1813-1865).

Other symbolic manipulative programs were appearing in the 1970's, including Reduce, Mathematika, Maple, and Macysma. Shenton used the Mathematika package at the University of Georgia in 1980 to 1990, especially the program including the conversion of series in powers of $n^{-1}$ into continued fractions. Accuracy was not a problem since output was in integer arithmetic.

To return to our present subject, Bowman was able to use Maple to cope with the skewness of m.l. estimators implementing the formula

$$
\mu_{32}\left(\hat{\theta}_{a}\right)=L^{\alpha \alpha} L^{\alpha \beta} L^{\alpha \gamma}\{[\alpha, \beta, \gamma]+3[\alpha \beta \gamma]+6[\alpha \beta, \gamma]\} .
$$

In the end, Bowman was able to reduce the problem of low order moments $\left(\mu_{11}^{\prime}, \mu_{12}^{\prime}, \mu_{21}, \mu_{22}, \mu_{32}, \mu_{43}\right)$ of a m.l. estimator to depend entirely on the probability function involved. The great advantage of the approach is seen when we consider the Weibull density. In this case 5th order derivatives appear (especially for $\mu_{12}^{\prime}$ ); for examples for square bracket terms such as

$$
\left[\theta_{1} \theta_{2} \theta_{3} \theta_{4} \theta_{5}\right]=E\left(\frac{\partial^{5} \log P}{\partial \theta_{1} \partial \theta_{2} \partial \theta_{3} \partial \theta_{4} \partial \theta_{5}}\right)
$$

and

$$
\left[\theta_{1} \theta_{1} \theta_{1} \theta_{1} \theta_{1}\right]=E\left(\frac{\partial \log P}{\partial \theta_{1}}\right)^{5}
$$

Terms like these are used in expressions for asymptotic moments. We now give the Maple program for the six basic asymptotic moments.

## 6. The Maple Program

### 6.1. New Maple program

We introduced the Maple program in Bowman and Shenton [24] to compute asymptotic variance and skewness of the m.l. estimators. We have extended the program to compute $N^{-1}$ and $N^{-2}$ biases, $N^{-2}$ variance, and $N^{-3}$ fourth central moment. The Maple program presented here is more general than the previous versions and could be easily
converted to any distribution's ('pf') with parameter number ('w'). Further, the user must decide on the value of ('lim') which depends on the range of the distribution, and for taking the expectation, use ('int') for integration of a continuous distribution and ('sum') for summation of a discrete distribution. The Maple program of the two parameter gamma distribution is presented in this section.

For example, to change from the two parameter gamma distribution to the three parameter gamma distribution, we carry out following:
(i) change ' $\mathrm{w}:=2$ ' to ' $\mathrm{w}:=3$ ';
(ii) change ' pf ' to 3 parameter gamma distribution;
(iii) change ' $\mathrm{t}:=[\mathrm{t} 1, \mathrm{t} 2]^{\prime}$ ' to ' $\mathrm{t}:=[\mathrm{t} 1, \mathrm{t} 2, \mathrm{t} 3]$ ';
(iv) add the third parameter value, to include this change in all the 'subs' statement.

To change from the two parameter gamma distribution to the two parameter Weibull distribution, change 'pf' accordingly and supply values of the two Weibull parameter values.

For the three parameter Weibull distribution follow the example of the two parameter gamma distribution to the three parameter gamma distribution. Bowman and Shenton [22] computed kurtosis of the three parameter Weibull distribution by writing FORTRAN program which consisted of 3500 or so lines and it was highly individualized. The Maple program is consisted of about 300 lines and is generalized, it is a great advancement.

Users could make further improvement by using only bias section of the program and correct a bias and run the rest of program using unbiased m.l. estimators.

### 6.2. Computer program

\#Find kurtosis, skewness, u2 and $u 1$ of ml estimators
\#number of parameters $=\mathrm{w}$
\#pf is a probability function or density (two parameter gamma density)
\#t is a vector of parameters $\mathrm{t} 1, \mathrm{t} 2, \ldots, \mathrm{tw}$
\#lim is the upper range of the distribution, constant or infinity
\#Output results are U11, U12, L (covariance matrix), U22, U32, rb1, \#U43, and K.

The case of the two parameter gamma distribution has been checked with the values in the table of Bowman and Shenton [18]. The case of the three parameter gamma distribution has been checked with the values in the paper of Bowman and Shenton [23]; see Subsection 4.2. The case of the two parameter Weibull Distribution has been checked with the paper of Bowman and Shenton [22]. The general usage of Maple language we refer to Heck [38].

### 6.3. An application

### 6.3.1. Mixture distribution

A mixture of a Poisson-Poisson distribution and a Poisson distribution is considered. The Poisson-Poisson distribution is a Lagrange distribution depending on two transformations, (i) $t=u g(t)$, and (ii) $f(t)=G(u), g(\cdot)$, and $G(\cdot)$ being probability functions for a Poisson random variable. Previous studies considered binomial, negative binomial, Gram-Charlier
and Pearson discrete distributions (Bowman and Shenton [19]). Here we consider solutions associated with sister chromatid exchange lymphocyte data, the data base quite large, the objective being to determine whether smoking played a significant role. We study for example, in the case associated with female nonsmokers (FNS), male nonsmokers (MNS), female smokers (FS), and male smokers (MS), deriving asymptotic biases, variances, skewness and kurtosis for the four m.l. estimators. The probability function is

$$
P\left(x ; t_{1}, t_{2}, t_{3}, t_{4}\right)=t_{4} t_{1}\left(t_{1}+t_{2} x\right)^{x-1} e^{-\left(t_{1}+t_{2} x\right)} / x!+\left(1-t_{4}\right) e^{-t_{3}} t_{3}^{x} / x!
$$

for $x=0,1, \ldots, 0<t_{4}<1,0 \leq t_{2}<1, t_{1}>0, t_{3}>0$. It will be seen that when $t_{2}=0$, the first component reduces to a Poisson probability function. Central moments are:

$$
\begin{aligned}
& \mu_{1}^{\prime}=\frac{t_{1}}{\left(1-t_{2}\right)}, \\
& \mu_{2}=\frac{t_{1}}{1-t_{2}}+\frac{t_{1} t_{2}}{\left(1-t_{2}\right)^{3}}, \\
& \mu_{3}=\frac{3 \mu_{2} t_{1}}{\left(1-t_{2}\right)^{2}}+\frac{t_{1}\left(1-t_{2}\right)+t_{1} t_{2}}{\left(1-t_{2}\right)^{3}}, \\
& \mu_{4}=3 \mu_{2}^{2}+\frac{\mu_{2}\left\{15 t_{1}^{2}+4 t_{2}\left(1-t_{2}\right)\right\}}{\left(1-t_{2}\right)^{4}}+\frac{t_{1}\left(1-6 t_{2}\right)}{\left(1-t_{2}\right)^{5}}+\frac{6 t_{1} t_{2}^{2}}{\left(1-t_{2}\right)^{6}} .
\end{aligned}
$$

Clearly $0 \leq t_{2}<1$.

### 6.3.2. The data sets and the analysis of data

The complete data set is given in Table 6.
Table 6. Distribution of SCE

## (a) Standard errors

These are given in Table 7 (parenthetic entries) and are due to Byers and Shenton [28]. Byers used the Splus program based on the m.l. estimator values of $t_{4}, t_{1}, t_{2}, t_{3}$, namely $\hat{t}_{4}, \hat{t}_{1}, \hat{t}_{2}, \hat{t}_{3}$. By and large our values (Table 8) of the standard errors (or standard deviation) agree with the Byers' values. Notice that, (i) the values of $t_{3}$ (the second component Poisson parameter) are all greater than twelve, yet the standard errors are all less than 1.3, (ii) the proportion in the mixture $t_{4}$ of the Poisson component ( $1-t_{4}$ ) is quite small, (iii) the first component in the mixture Poisson-Poisson is basically Poisson, $t_{2}$ being small.

## (b) Bias (Table 8)

Using first and second order terms in $E(\hat{t})$, the bias for the estimators is negligible except for the proportion parameter $t_{4}$, for which there is a correction of -0.01 for FS. Note that here the sample size is $N=1500$, the smallest in the group of four.

## (c) Skewness and kurtosis

For the Poisson-Poisson components $t_{1}$ and $t_{2}$, if $t_{2}=0$ the $P \cap P$ reduces to a Poisson probability function with parameter $t_{1}$. From the Table 7, $t_{1}$ is about 7.0 with small sigma; also $\sqrt{\beta_{1}}$ and $\beta_{2}$ are nearly normal values $(0,3)$. Hence we may assume that the distribution is
approximately normal. Looking at $t_{2}$ (a discrepancy parameter from the Poisson), it is small in comparison to $t_{1}$, with small variance; asymptotic normality is quite possible. These remarks apply to the four groups, FNS, MNS, FS, and MS.

Now $t_{3}$ relates to the Poisson of the second component in the mixture; it is in the range 12-17 and its standard deviation is small in comparison. Again asymptotic normality is acceptable.

The skewness of the proportion parameter $t_{4}$ is negative in all the four groups, but for MS the kurtosis indicate a platykurtic distribution. The skewness cannot be neglected and is largest in value for FNS.

Altogether, the sample sizes are large, and the first component in the mixture is close to a Poisson distribution, whereas there is a small proportion of the second component which is Poisson with large parameter.

For m.l. estimators, variance and skewness have been implemented using the Maple system. The asymptotic variance of the four parameter estimators check out against a previous study by Byers and Shenton [28]; in this paper Byers set up a Splus program to compute the standard errors of the four parameter model of SCE data.

## 7. Conclusions

Maple symbolic programs have been set up for the moments of a m.l. estimator $\hat{\theta}_{a}$, given a density (or probability function) defined by $s$ parameters $\theta_{1}, \theta_{2}, \ldots, \theta_{s}$. Moments of the corresponding random variable are assumed to exist.

Moments such as $\mu_{r s}\left(\hat{\theta}_{a}\right)$ are considered; here $r$ refers to the $r$ th central moment, $s$ to the coefficient $N^{-s}$ in this moment. The bias formula is expanded to $N^{-2}$, variance to $N^{-2}, \mu_{3}$ to $N^{-2}$, and $\mu_{4}$ to $N^{-3}$.

Asymptotic series are set up; for example

$$
E\left(\hat{\theta}_{a}\right) \sim \theta_{a}+\frac{\phi_{1}(\underline{\theta})}{N}+\frac{\phi_{2}(\underline{\theta})}{N^{2}}+\cdots \quad(N \rightarrow \infty)
$$

and similarly for $E\left(\hat{\theta}_{a}-\theta_{a}\right)^{m}, m=2,3,4$.
Advances in symbolic languages are sketched. It is quite possible that the first use of a digital computer to solve a perturbation series in celestial mechanics occurred about 50 or so years ago. Van Dyke [55] mentioned the case of a French astronomer who basically considered a quintuple Taylor series carried out to a term of order nine.

One of us has developed the Maple programs given here. The main results concern $\mu_{32}\left(\hat{\theta}_{a}\right)$, and $\mu_{43}\left(\hat{\theta}_{a}\right)$ for m.l. estimators. In our example of an application, the density ('pf') can involve 4 parameters, and extensions to 5 or more parameters are possible.

A four parameter discrete distribution is given as an example. Here standard errors check up from an independent approach.

The asymptotic skewness, being location free, and scale free, is an addition to our knowledge of the behavior of m.l. estimators. The basic requirement is the existence of expectation of logarithmic derivatives of the density or probability function.

## Appendix

## A. The Gamma Function and Asymptotic Series

## A.1. Euler

Both the gamma distribution and the Weibull distribution have strong associations with the gamma functions. How do asymptotics appear?

The gamma integral,

$$
\Gamma(z)=\int_{0}^{\infty} e^{-t} t^{z-1} d t \quad(\Re(z)>0)
$$

is due to Euler (1707-1783). It is called, according to Whittaker and Watson [57], Euler's integral of the second kind.

## A.2. Binet

In the early part of the 19th century, Binet [5] initiated work on $\ln \Gamma(z)$, giving the expression

$$
\begin{align*}
\ln \Gamma(z)= & \left(z-\frac{1}{2}\right) \ln z-z+\frac{1}{2} \ln (2 \pi) \\
& +\int_{0}^{\infty}\left(\frac{1}{2}-\frac{1}{t}+\frac{1}{e^{t}-1}\right) \frac{e^{-t z}}{t} d t \quad(\mathfrak{R}(z)>0) \tag{12}
\end{align*}
$$

Some time later Binet produced the improved result

$$
\ln \Gamma(z)=\left(z-\frac{1}{2}\right) \ln z-z+\frac{1}{2} \ln (2 \pi)+2 \int_{0}^{\infty} \frac{\arctan (t / z)}{e^{-2 \pi t}-1} d t \quad(\mathfrak{R}(z)>0)
$$

## A.3. The "Remainder" term $J(z)$

The integral in (11) may be written as

$$
2 \int_{0}^{\infty} \frac{(\arctan t / z) e^{-2 \pi t}}{1-e^{-2 \pi t}} d t
$$

and by integration by parts becomes

$$
\frac{1}{\pi} \int_{0}^{\infty}\left(\ln \frac{1}{1-e^{-2 \pi t}}\right) \frac{z d t}{z^{2}+t^{2}} \quad(\mathfrak{R}(z)>0)
$$

Hence

$$
\ln \Gamma(z)=I(z)+J(z)
$$

where

$$
I(z)=\left(z-\frac{1}{2}\right) \ln z-z+\frac{1}{2} \ln (2 \pi)
$$

$$
J(z)=-\frac{1}{\pi} \int_{0}^{\infty}\left\{\ln \left(1-e^{-2 \pi t}\right)\right\} \frac{z d t}{z^{2}+t^{2}} \quad(\Re>0)
$$

## A.4. Series for $J(z)$

Now $J(z)$ can, at least formally, be expanded in series in descending powers of $z$, i.e.,

$$
J(z)=\frac{c_{0}}{z}-\frac{c_{1}}{z^{2}}+\frac{c_{2}}{z^{3}}-\cdots
$$

where

$$
\begin{aligned}
& c_{0}=-\frac{1}{\pi} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi t}\right) d t \\
& c_{1}=-\frac{1}{\pi} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi t}\right) t^{2} d t \\
& c_{s}=-\frac{1}{\pi} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi t}\right) t^{2 s} d t, \quad(s=0,1, \ldots)
\end{aligned}
$$

Expanding the logarithmic terms, we have, with $2 \pi t=u$,

$$
\begin{aligned}
c_{s} & =\frac{1}{\pi} \int_{0}^{\infty}\left(\frac{1}{2 \pi}\right)\left(\ln \frac{1}{1-e^{-u}}\right)\left(\frac{u}{2 \pi}\right)^{2 s} d u \\
& =\frac{1}{\pi(2 \pi)^{2 s+1}} \int_{0}^{\infty}\left(e^{-u}+\frac{e^{-2 u}}{2}+\frac{e^{-3 u}}{3}+\frac{e^{-4 u}}{4}+\cdots\right) u^{2 s} d u \\
& =\frac{(2 s)!}{\pi(2 \pi)^{2 s+1}}\left(1+\frac{1}{2^{2 s+2}}+\frac{1}{3^{3 s+2}}+\frac{1}{4^{2 s+2}}+\cdots\right) \\
& =\frac{(2 s)!}{\pi(2 \pi)^{2 s+1}} \zeta(2 s+2)
\end{aligned}
$$

in terms of the Riemann zeta function. From N.B.S. (1970, p. 807),

$$
\zeta(2 s+2)=(2 \pi)^{2 s+2}\left|B_{2 s+2}\right| /\{2(2 s+2)!\}
$$

so that

$$
c_{s}=\frac{\left|B_{2 s+2}\right|}{(2 s+2)(2 s+1)} \quad(s=0,1, \ldots)
$$

in terms of Bernoulli numbers,

$$
\begin{aligned}
& B_{0}=1, \quad B_{1}=-\frac{1}{2}, \quad B_{2}=\frac{1}{6}, \quad B_{3}=0, \quad B_{4}=-\frac{1}{30} \\
& B_{5}=0, \quad B_{6}=\frac{1}{42}, \quad B_{7}=0, \quad B_{8}=-\frac{1}{30}
\end{aligned}
$$

Hence there is the asymptotic series for $J(z)$, namely

$$
\begin{align*}
J(z) \sim & \frac{\left|B_{2}\right|}{1 \cdot 2 \cdot z}-\frac{\left|B_{4}\right|}{3 \cdot 4 \cdot z^{3}}+\frac{\left|B_{6}\right|}{5 \cdot 6 \cdot z^{5}}-\frac{\left|B_{8}\right|}{7 \cdot 8 \cdot z^{7}}+\cdots \quad(z \rightarrow \infty \text { in }|z|<\pi) \\
& \sim \frac{1}{12 z}-\frac{1}{360 z^{3}}+\frac{1}{1260 z^{5}}-\frac{1}{1680 z^{7}}+\frac{5}{5940 z^{9}} \tag{13}
\end{align*}
$$

## A.5. Semi-convergent series

This series (13) is not divergent, but is semi-convergent, i.e., the error in using $s$ terms is less in value than the first term omitted provided $z$ is real and positive. For we have, formally the remainder after $s$ terms is

$$
\begin{aligned}
R_{s}(z) & =(-1)^{s}\left\{\frac{c_{s}}{z^{2 s+1}}-\frac{c_{s+1}}{z^{2 s+3}}+\cdots\right\} \\
& =\frac{(-1)^{s+1}}{\pi} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi u}\right)\left\{\frac{u^{2 s}}{z^{2 s+1}}-\frac{u^{2 s+2}}{z^{2 s+3}}+\cdots\right\} d u \\
& =\frac{(-1)^{s+1}}{\pi z} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi u}\right) \frac{u^{2 s}}{z^{2 s}}\left(1+\frac{u^{2}}{z^{2}}\right)^{-1} d u \\
& =\frac{(-1)^{s+1}}{\pi z} \int_{0}^{\infty} \ln \left(1-e^{-2 \pi u}\right) \frac{u^{2 s}}{z^{2 s}} \frac{z^{2}}{z^{2}+u^{2}} d u
\end{aligned}
$$

for $z$ real and positive. Thus

$$
\left|R_{s}(z)\right|<\frac{1}{\pi z} \int_{0}^{\infty}\left(\ln \frac{1}{1-e^{-2 \pi u}}\right) \frac{u^{2 s}}{z^{2 s}} d u=\frac{c_{s}}{z^{2 s+1}}
$$

i.e., the first term omitted.

## A.6. G. H. Hardy and $\log n$ !

Hardy [37] considered the expression

$$
\log n!=\sum_{1}^{n} \log m=\left(n-\frac{1}{2}\right) \log n-n+C+\frac{B_{1}}{1 \cdot 2 n}+\frac{B_{2}}{3 \cdot 4 n^{3}}+\frac{B_{3}}{5 \cdot 6 n^{5}}+\cdots,
$$

where

$$
C=1-\frac{B_{1}}{1 \cdot 2}+\frac{B_{2}}{3 \cdot 4}+\frac{B_{3}}{5 \cdot 6}+\frac{B_{4}}{7 \cdot 8}+\cdots .
$$

Hardy remarks that the series is semi-convergent and can be used to calculate $\log n!$, and $C$ with $z=1$. Note that he uses

$$
B_{1}=\frac{1}{6}, B_{2}=\frac{1}{30}, B_{3}=\frac{1}{42}, B_{4}=\frac{1}{30}, B_{5}=\frac{5}{66} .
$$

The series for $C$ may be set up from our expression in (13); since in this expression the fifth term is larger in value than the forth, the first four showing a decreasing sequence in values, we use

$$
C \sim 1-\frac{1}{12}+\frac{1}{360}-\frac{1}{1260}=0.91865
$$

which agrees with $\frac{1}{2} \ln (2 \pi)$ to 3 significant digits.
There are surprising inconsistencies in Hardy's short note (Hardy [37, p. 329]). To use the equality symbol with no mention of an appropriate domain is rather surprising.

Returning to $\ln \Gamma(z)$, Wall's [56] account and association with the theory of continued fractions is interesting. However there is no mention of the fact that Stieltjes discussed the continued fraction form in 1889; Wall however includes two new partial numerators in the continued fraction.

There are two errors to note on Wall's account. First in his (93.5) the sign should be negative. Second the infinite series for $J(z)$ in terms of Bernoulli numbers is not totally divergent.

# THE APPROXIMATE DISTRIBUTION OF FOUR MOMENT STATISTICS FROM TYPE III DISTRIBUTIONS 

K. O. Bowman<br>Oak Ridge National Laboratory<br>P. O. Box 2009<br>L. R. Shenton University of Georgia<br>Athens, Georgia 30602<br>Oak Ridge, Tennessee 37831-8083

Key Words and Phrases: continued fractions; divergent series; moments; multivariate Taylor series; sample moments; simulation cycles.

#### Abstract

Taylor series in the sample size are set up for the first four moments of the standard deviation, skewness, kurtosis, and coefficient of variation, the populations being $\chi^{2}$ (gamma, Pearson Type III). These moments being out of reach of purely mathematical development, the study proceeds along two independent lines. For the one, simulation methods are used, an attempt being made to fix a cycle length to ensure some stability - this cycles length is pivoted on the fourth moment of the kurtosis, an expression involving sixteenth powers of the basic $\chi^{2}$. random variable. The second line of attack uses the Taylor moment series which are taken out to at most sixty terms in the total derivatives. An algorithm is used to derive the expectation of a product of powers of elements which consist of non-central sample deviates; there are four of these involved in the kurtosis, three in the skewness, and two in the standard deviation. There is an added parameter for sample size. This expectation of products of powers of sample deviates generates a set of coefficients, each coefficient multiplied by a power of $n^{-1}$; the larger the moment product, the greater is the span of the powers of $n^{-1}$. If a final moment series is desired to include all contributions up to $n^{-s}$, then at least $2 s$ terms will be required in the Taylor expansion; moreover the

series may turn out to be divergent as far as can be judged by the behavior of the terms computed. At this point, since the series are not seen to be one-signed, and since divergence is not too chaotic (as far as the triple factorial, say), rational fraction sequences are set up to dilute divergence (or accelerate apparent convergence); the approach is often successful but there are problems with small sample sizes and large skewness of the population sampled. Lastly, gross errors in relying on basic asymptotes are noted. The study brings out unusual confluences computer oriented numerical analysis, distributional theory and approximation, and the power of rational fraction a divergency reducing tools.

# PARAMETER ESTIMATION FOR THE BETA DISTRIBUTION 

K. O. BOWMAN<br>Mathematical Science Section, Engineering Physics and Mathematics, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6367 L. R. SHENTON<br>University of Georgia, Athens, Georgia 30602<br>(Received November 29, 1990: in final form March 18, 1992)

Moment estimators, based on the first two sample moments, for the two index parameters of the beta density (known end-points) are studied. Four moments of these estimators are set up using Computer Oriented Extended Taylor Series (COETS) to 60 terms followed by rational fraction approximations. These indicate, over a limited parameter space, that allowing for simplicity of calculation and other characteristics they are preferable to maximum likelihood estimators.

#### Abstract

Bowman et al. [K. O. Bowman, M. A. Kastenbaum, L. R. Shenton, Fitting multiparameter distributions to SEC data, Mutation Res., 358 (1996) 15-24] showed how discrete Pearson and discrete Johnson translation-system distributions may be fitted to sister chromatid exchange (SCE) data presented by Bender et al. [M. A. Bender, R. J. Preston, R. C. Leonard, B. E. Pyatt, P. C. Gooch, On the distribution of spontaneous SCE in human peripheral blood lymphocytes, Mutation Res. 281 (1992) 227-232]. When their performances were measured by the chisquare test of goodness of fit, these distributions proved to be only moderately better alternatives to the poorly fitting Poisson, binomial, and negative binomial distributions. In this paper we extend our search for better characterizations of the SCE data by calling upon the GramCharlier type B approximation of the negative binomial distribution. We introduce an innovative extension of methods described in a little-known paper by Aitken and Gonin [A. C. Aiken, H. T. Gonin, On fourfold sampling with and without replacement, Proc. R. Soc. Edinburgh, 55 (1934) 114-125], and show how a theorem by Cramér [H. Cramér, Mathematical Methods of Statistics, Princeton Univ. Press, 1946], relating to the scale factor $m_{2} / m_{1}^{\prime}$ and its asymptotic distribution may be used to discriminate between smokers and non-smokers of the same gender.

#### Abstract

In previous papers (Bowman and Shenton, 1998, 1999a) we have given expressions for the asymptotic skewness and kurtosis for maximum likelihood estimators in the case of several parameters. Skewness is measured by the third standardized central moment, and kurtosis by the fourth standardized central moment. Moments of the basic structure are assumed to exist. The overarching entity is the covariance matrix (Hessian form), and elements of its inverse. These entities involve Stieltjes integrals relating to sums of products of multiple derivatives linked to the basic structure. The first paper dealt with skewness and gives a simple expression readily computerized. The second paper is devoted to the forth standardized central moment and although a certain simplification is discovered, the resulting formula is still somewhat complicated. It is surprising to find that the asymptotic kurtosis in general requires the evaluation of several hundred components. The present paper studies cases involving one, two, and three parameters and mentions strategies aimed at avoiding algebraic and numerical errors.

#### Abstract

In general, when moments exist, the dominant term in the fourth central moment of an estimator is three times the square of the asymptotic variance; this leads to the value three for the asymptotic kurtosis. Working on the approach given in Bowman and Shenton (1998) we now complete the basic asymptotic moment profile by giving an expression for the third order term in the fourth central moment of a maximum likelihood estimator, assuming the existence of derivatives of a density and also the existence of the covariance matrix inverse. A four moment distributional model, such as the Pearson system, or Johnson translation system, may be used to approximate percentage points of the estimators.

# MAXIMUM LIKELIHOOD AND THE WEIBULL DISTRIBUTION 

K. O. BOWMAN and L. R. SHENTON<br>Computer Science and Mathematics Division<br>Oak Ridge National Laboratory, P. O. Box 2008, Oak Ridge Tennessee 37931-6367, U.S.A.<br>e-mail: bowmanko@ornl.gov<br>Department of Statistics University of Georgia Athens, Georgia 30602<br>U. S. A.

#### Abstract

The Weibull distribution has three parameters, location $a$, scale $b$ and shape $c$. Maximum likelihood estimators are $\hat{a}, \hat{b}, \hat{c}$, and solutions may not always exist; for example the location estimate $\hat{\alpha}$ must be less than the smallest member of the sample. We consider three estimation problems: (1) Estimation of one parameter when the other two are assumed to be known. (2) Estimating the scale and shape parameters when the location parameter is known. (3) Estimating the three parameters simultaneously.

Results being based on the covariance matrix and its cofactors, we give explicit expressions for the asymptotic bias, 2 nd order variances, skewness to order $1 / \sqrt{N}$, and asymptotic kurtosis to order $1 / N, N$ being the sample size. Except for the simultaneous estimation of $a, b, c$, the expressions for these asymptotic moments and moment ratios are simple in form involving gamma and Riemann Zeta functions. They provide a new basic supplement to our knowledge of maximum likelihood estimator moments.

A surprising discovery is the part played by the location parameter whenever it has to be estimated. For the three parameter estimation case it is already known that asymptotic covariance only exist if $c>2$. It turns out that the asymptotic skewness only exist if $c>3$, and the asymptotic kurtosis only exist $c>4$. This applies to the asymptotic distribution of $\hat{a}, \hat{b}$, and $\hat{c}$. The source of this characteristic is the singularity appearing in the expectation of logarithmic derivatives. When less than 3 parameters are to be estimated the problem arises whenever $\hat{a}$ intrudes.

For the 3 parameter case, a new expression is developed for the asymptotic variance of $\hat{c}$. Lastly, wherever possible simulation studies are invoked for verification purposes.

# Weibull distributions when the shape parameter is defined 

K. O. Bowman ${ }^{a}$, L. R. Shenton ${ }^{b}$<br>${ }^{a}$ Computer Science and Mathematics Division, Building 6012, Oak Ridge National Laboratory, P. O. Box 2008, MS-6367, Oak Ridge, TN 37831-6367, USA<br>${ }^{b}$ Department of Statistics, University of Georgia, Athens, GA 30602, USA

Received 1 April 2000; received in revised form 1 October 2000.

#### Abstract

The Weibull distribution, depending on parameters of location, scale, and shape, is often useful as a model for fracture data sets. If the location parameter is to be estimated then we have shown that maximum likelihood methods are not recommended. In the data set considered here the shape parameter is known to lie between 2 and 3 or so. We therefore studied the 2 parameter model for which the shape parameter is known, or has a probability structure. Simple moment estimators are used and some moments of these are studied and verified by simulation.

Key words: Envelope distribution, moment estimator, moments of sample moments, Padé sequences, Taylor series, unbiased estimators.

# PROBLEMS WITH MAXIMUM LIKELIHOOD ESTIMATION AND THE 3 PARAMETER GAMMA DISTRIBUTION 

K. O. BOWMAN ${ }^{a}$ and L. R. SHENTON ${ }^{b}$<br>${ }^{a}$ Computer Science and Mathematics Division, Oak Ridge National Laboratory, P. O. Box 2008, MS-6367, Oak Ridge, Tennessee 37831-6367;<br>${ }^{b}$ Department of Statistics, University of Georgia, Athens, Georgis 30602

(Received 21 March 2001; In final form 3 October 2001)

The three parameters involved are scale $a$, shape $\rho$, and location $s$. Maximum likelihood estimators are ( $\hat{\alpha}, \hat{\rho}, \hat{s}$ ). Using recent work on the second order variances, skewness, and kurtosis we establish the facts, that if the location parameter $s$ is to be estimated, then the asymptotic variances only exist if $\rho>2$, asymptotic skewness only exists if $\rho>3$, and 2nd order variances and third order fourth central moments only exist if $\rho>4$. The result of these limitations is that in general very large sample sizes may be needed to avoid inference problems. We also include new continued fractions for the asymptotic covariances of the maximum likelihood estimators considered.

## USE OF LAGRANGE EXPANSION FOR GENERATING DISCRETE GENERALIZED PROBABILITY DISTRIBUTIONS

## P. C. CONSUL and L. R. SHENTON

Abstract. Considering $g(t)$ and $f(t)$ as two probability generating functions defined on nonnegative integers with $g(0) \neq 0$. We use Lagrange's expansion, together with the transformation $t=u \cdot g(t)$ to define families of discrete generalized probability distributions by the name of Lagrange distributions as

$$
\begin{aligned}
& \operatorname{Pr}[X=0]=L(g: f: 0)=f(0), \\
& \operatorname{Pr}[X=x]=L(g: f: x)=\left.\frac{1}{x!} \frac{d^{x-1}}{d t^{x-1}}\left\{(g(t))^{x} \cdot f^{\prime}(t)\right\}\right|_{t=0}
\end{aligned}
$$

for $x=1,2,3, \ldots$, where the different families are generated by assigning different values to $g(t)$ and $f(t)$. General formulas for writing down the central moments of Lagrange distributions are obtained and it is shown that they satisfy the convolution property. The double binomial family of Lagrange distributions is studied in greater detail as it gives a large number of discrete distributions, including Borel-Tanner distribution, Haight's distribution, generalized Poisson and generalized negative binomial distributions, as particular cases.

# MAXIMUM LIKELIHOOD ESTIMATION FOR THE PARAMETERS OF THE HERMITE DISTRIBUTION 

By Y. C. PATEL, L. R. SHENTON<br>University of Georgia<br>and K. O. BOWMAN<br>Oak Ridge National Laboratory, U. S. A.

Properties of the maximum likelihood estimators of the parameters $(a, b)$ in the Hermite distribution, with probability generating function $\exp \left\{a(t-1)+b\left(t^{2}-1\right)\right\}$ are discussed. Numerical assessments of the first and second order coefficients in the biases and covariances are given for a limited region of the parameter space.

Rep. Stat. Appl. Res., JUSE
Vol. 17, No. 3, 1970

# TABLES OF THE MOMENTS OF THE MAXIMUM LIKELIHOOD ESTIMATORS OF THE TWO PARAMETER GAMMA DISTRIBUTION 

By L. R. Shenton<br>Professor of Statistics, Computer Center, University of Georgia, Athens, Georgia 30601<br>K. O. Bowman<br>Mathematical Statistician, Computer Technology Center, Union Carbide Corporation, Nuclear Division<br>Oak Ridge, Tennessee, USA

The moments of the maximum likelihood estimators of the parameters $\rho, a$ for the gamma density $f(x)=k(x / a)^{\rho-1} \exp (-x / a)$ are briefly tabulated. These include the biases $E(\hat{\rho}-\rho) / \rho, E(\hat{\alpha}-a) / a$, the variances $\operatorname{Var}(\hat{\rho} / \rho), \operatorname{Var}(\hat{\alpha} / a)$, skewness and kurtosis. The range of values considered is approximately $\rho=0.2$ to 3.0 and $n$ (the sample size) lying between 12 and 100. Some comparisons of the moments with the usual first-order asymptotic values are made.
